

Raster Analysis

Ben DeVries, Jan Verbesselt, Loic Dutrieux, Sytze de Bruin

October 9, 2013

Abstract

In this tutorial, we will explore the raster package and other related packages used for typical raster analyses. We will first look at analysis of RasterLayer objects, exploring functions having to do with raster algebra, focal and zonal statistics and other operations. We will then explore spatio-temporal analysis of raster data using RasterBrick objects. Here, we will extract time series data from a RasterBrick object and derive temporal statistics from these data.

1. perform typical image preprocessing operations (apply a mask, calculate ndvi, etc.)
2. overlaying with geodata and calculating zonal statistics
3. explore a raster brick by plotting layers and layers statistics
4. perform raster brick operations to derive stats (e.g. %no-data in the time series)
5. extract pixel time series and derive various statistics

1 The raster package

The raster package is an essential tool for raster-based analysis in R. Here you will find functions which are fundamental to image analysis. The raster package documentation is a good place to begin exploring the possibilities of image analysis within R. There is also an excellent vignette available at <http://cran.r-project.org/web/packages/raster/vignettes/Raster.pdf>.

2 The Landsat archive

Since being released to the public, the Landsat data archive has become an invaluable tool for environmental monitoring. With a historical archive reaching back to the 1970's, the release of these data has resulted in a spur of time series based methods. In this tutorial, we will work with time series data from the Landsat 7 Enhanced Thematic Mapper (ETM+) sensor.

3 Manipulating raster data

This section will cover some of the following areas:

- calculate % of no data in a raster
- crop a raster based on a defined extent, another object's extent, or interactively using `drawExtent()`

- working with the `calc()` and `overlay()` functions:
 - load and apply a mask (cloud mask)
 - raster algebra with two or more raster layers
- focal operations; create a function to 'sieve' a raster object (remove lone pixels)
- create an areal filter for a raster by converting to a `SpatialPolygon`, removing small features and back to raster using the `rasterize()` function
- zonal statistics using other geodata (Biosphere Reserve zones, administrative zones, etc...)
- reclassifying (stratifying) a raster based on elevation data (SRTM or ASTER2)

4 Working with multilayered raster data

When working with multispectral or multitemporal raster data, it is convenient to represent multiple raster layers as a single object in R. R works with two types of multilayer raster objects: stacks and bricks. The main difference between the two is that raster stacks can be read from several different data sources (files) and bricks are read from a single file (e.g. a multiband GeoTIFF).

A raster brick from a small area within the Kafa Biosphere Reserve in Southern Ethiopia can be found in the `rasta` package. Set the working directory to the packages home folder and load the raster brick from file by

```
> setwd('path/to/rasta/package') # set this to the appropriate directory
> tura <- brick('inst/extdata/tura.grd')

> # inspect the data
> class(tura) # the object's class

[1] "RasterBrick"
attr(,"package")
[1] "raster"

> projection(tura) # the projection

[1] "+proj=utm +zone=36 +ellps=WGS84 +units=m +no_defs"

> res(tura) # the spatial resolution (x, y)

[1] 30 30

> extent(tura) # the extent of the raster brick

class      : Extent
xmin       : 819105
xmax       : 823395
ymin       : 827745
ymax       : 832185
```

Extracting scene information

This RasterBrick was read from a .grd file. One advantage of this file format (over the GeoTIFF format, for example) is the fact that the specific names of the raster layers making up this brick have been preserved, a feature which is important for identifying raster layers, especially when doing time series analysis (where you need to know the values on the time axis). This RasterBrick was prepared from a Landsat 7 ETM+ time series, and the original scene names were inserted as layer names.

```
> names(tura) # displays the names of all layers in the tura RasterBrick
```

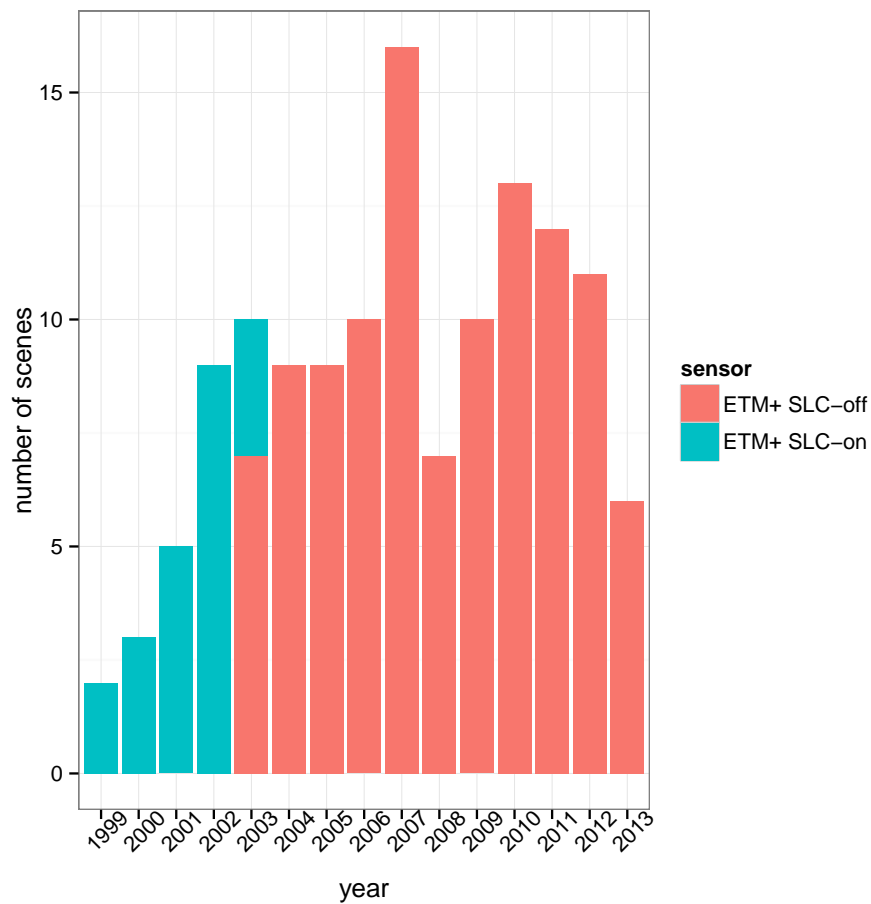

We can parse these names to extract information from them. The first 3 characters indicate which sensor the data come from, with 'LE7' indicating Landsat 7 ETM+ and 'LT5' or 'LT4' indicating Landsat 5 and Landsat 4 TM, respectively. The following 6 characters indicate the path and row (3 digits each), according to the WGS system. The following 7 digits represent the date. The date is formatted in such a way that it equals the year + the julian day. For example, February 5th 2001, aka the 36th day of 2001, would be '2001036'.

```
> # display the 1st 3 characters of the layer names
> sensor <- substr(names(tura), 1, 3)
> print(sensor)
> # display the path and row as numeric vectors in the form (path,row)
> path <- as.numeric(substr(names(tura), 4, 6))
> row <- as.numeric(substr(names(tura), 7, 9))
> print(paste(path, row, sep = ","))
> # display the date
> dates <- substr(names(tura), 10, 16)
> print(dates)
> # format the date in the format yyyy-mm-dd
> as.Date(dates, format = "%Y%j")
```

There is a function in the *rasta* package, `getSceneinfo()` that will parse these names and output a data.frame with all of these attributes.

```
> sceneinfo <- getSceneinfo(names(tura))
> print(sceneinfo)
> # add a 'year' column to the sceneinfo dataframe and plot #scenes/year
> sceneinfo$year <- factor(substr(sceneinfo$date, 1, 4), levels = c(1999:2013))

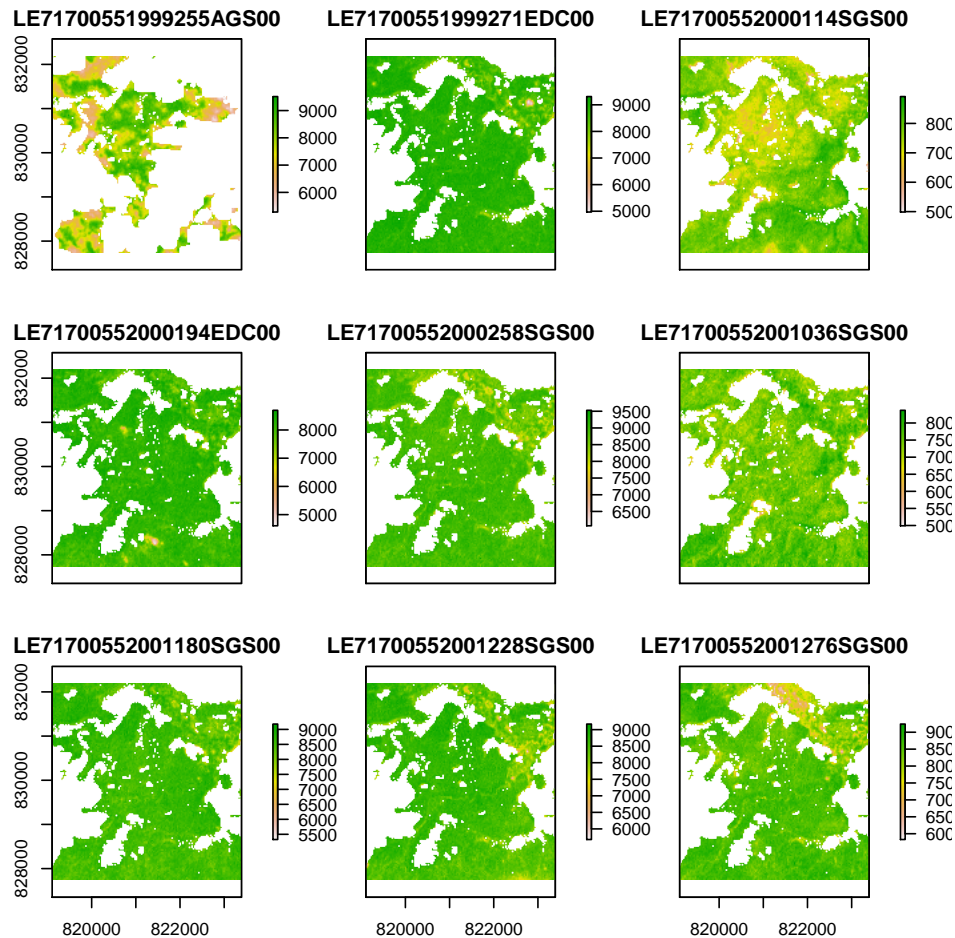

> # barplot with number of scenes per year
> library(ggplot2)
> ggplot(data = sceneinfo, aes(x = year, fill = sensor)) +
+   geom_bar() +
+   labs(y = "number of scenes") +
+   theme_bw() +
+   theme(axis.text.x = element_text(angle = 45))
```

Plotting RasterBricks

A RasterBrick can be plotted just as a RasterLayer, and the graphics device will automatically split into panels to accommodate the layers (to an extent: R will not attempt to plot 100 layers at once!). To plot the first 9 layers:

```
> plot(tura, c(1:9))
> # alternatively, you can use [[]] notation to specify layers
> plot(tura[[1:9]])
> # use the information from sceneinfo data.frame to clean up the titles
> plot(tura[[1:9]], main = sceneinfo$date[c(1:9)])
```

Unfortunately, the scale is different for each of the layers, making it impossible to make any meaningful comparison between the raster layers. This problem can be solved by specifying a `breaks` argument in the `plot()` function.

```
> # we need to define the breaks to harmonize the scales (to make the plots comparable)
> bks <- seq(0, 10000, by = 2000) # (arbitrarily) define the breaks
> # we also need to redefine the colour palette to match the breaks
> cols <- rev(terrain.colors(length(bks))) # col = rev(terrain.colors(255)) is the default
> # (opt: check out the RColorBrewer package for other colour palettes)
> # plot again with the new parameters
> plot(tura[[1:9]], main = sceneinfo$date[1:9], breaks = bks, col = cols)
```

Alternatively, the `rasterVis` package has some enhanced plotting functionality for raster objects, including the `levelplot()` function, which automatically provides a common scale for the layers.

```
> library(rasterVis)
> levelplot(tura[[1:6]])
> # NOTE:
> # for rasterVis plots we must use the [[]] notation for extracting layers
```

```
> # providing titles to the layers is done using the 'names.attr' argument in place of 'ma
> levelplot(tura[[1:6]], names.attr = sceneinfo$date[1:6])
```

This plot gives us a common scale which allows us to compare values (and perhaps detect trends) from layer to layer. In the above plot, the layer titles do not look very nice – we will solve that problem a bit later.

The rasterVis package has integrated plot types from other packages with the raster package to allow for enhanced analysis of raster data.

```
> # histograms of the first 6 layers
> histogram(tura[[1:6]])
> # box and whisker plot of the first 9 layers
> bwplot(tura[[1:9]])
```

More examples from the rasterVis package can be found @ <http://oscarperpinan.github.io/rastervis/>

Calculating data loss

In this RasterBrick, the layers have all been individually preprocessed from the raw data format into NDVI values. Part of this process was to remove all pixels obscured by clouds or SLC-off gaps (for any ETM+ data acquired after March 2003). For this reason, it may be useful to know how much of the data has been lost to cloud cover and SLC gaps. First, we will calculate the percentage of no-data pixels in each of the layers using the freq() function. freq() returns a table (matrix) of counts for each value in the raster layer. It may be easier to represent this as a data.frame to access column values.

```
> # try for one layer first
> y <- freq(tura[[1]]) # this is a matrix
> y <- as.data.frame(y)
> # how many NA's are there in this table?
> y$count[is.na(y$value)]
```

```
[1] 13687
```

```
> # alternatively, using the with() function:
> with(y, count[is.na(value)])
```

```
[1] 13687
```

```
> # as a %
> with(y, count[is.na(value)]) / ncell(tura[[1]]) * 100
```

```
[1] 64.67114
```

```
> # apply this over all layers in the RasterBrick
> # first, prepare a numeric vector to be 'filled' in
> nas <- vector(mode = 'numeric', length = nlayers(tura))
> for(i in 1:nlayers(tura)){
```

```

+ y <- as.data.frame(freq(tura[[i]]))
+ nas[i] <- with(y, count[is.na(value)]) / ncell(tura[[i]]) * 100
+ }
> # add this vector as a column in the sceneinfo data.frame
> sceneinfo$nodata <- nas

> # plot these values
> ggplot(data = sceneinfo, aes(x = date, y = nodata, shape = sensor)) +
+   geom_point(size = 2) +
+   labs(y = "% nodata") +
+   theme_bw()

```

We have now derived some highly valuable information about our time series. For example, we may want to select an image from our time series with relatively little cloud cover to perform a classification. For further time series analysis, the layers with 100% data loss will be of no use to us, so it may make sense to get rid of these layers.

```

> # which layers have 100% data loss?
> which(sceneinfo$nodata == 100)

[1] 13 22 25 34 35 41 42 44 54 62 75 79 95 96 104 108 120 129

```

```

> # supply these indices to the dropLayer() command to get rid of these layers
> tura <- dropLayer(tura, which(sceneinfo$nodata == 100))
> # redefine our sceneinfo data.frame as well
> sceneinfo <- sceneinfo[which(sceneinfo$nodata != 100), ]
> # optional: remake the previous ggplots with this new dataframe

```

With some analyses, it may also be desirable to apply a no-data threshold per scene, in which case layer indices would be selected by:

```

> which(sceneinfo$nodata > some_threshold)

```

In some cases, there may be parts of the study area with more significant data loss due to persistent cloud cover or higher incidence of SLC-off gaps. To map the spatial distribution of data loss, we need to calculate the % of NA in the time series for each *pixel* (ie. looking 'through' the pixel along the time axis). To do this, it is convenient to use the `calc()` function and supply a special function which will count the number of NA's for each pixel along the time axis, divide it by the total number of data in the pixel time series, and output a percentage. `calc()` will output a raster with a percentage no-data value for each pixel.

```

> # calc() will apply a function over each pixel
> # in this case, each pixel represents a time series of NDVI values
> # e.g. all values of the 53rd pixel in the raster grid:
> y <- as.numeric(tura[53])
> # how many of these values have been masked (NA)?
> length(y[is.na(y)])

```

```

[1] 18

```

```

> # as a %
> length(y[is.na(y)]) / length(y) * 100

```

```

[1] 15.78947

```

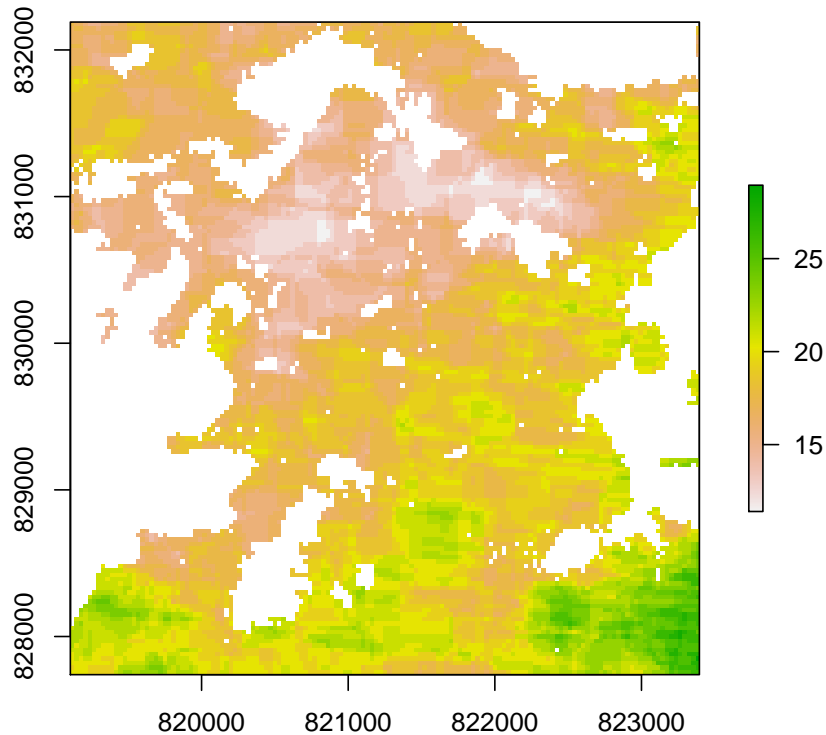

```

> # now wrap this in a calc() to apply over all pixels of the RasterBrick
> nodata <- calc(tura, fun = function(x) length(x[is.na(x)]) / length(x) * 100)

```

```
> # block out pixels with 100% data loss (these have already been masked)
> nodata[nodata == 100] <- NA
```

5 Times Series Analysis

- making time series plots for selected pixels (interactively or otherwise)
- deriving time series statistics
 - linear regression from pixel time series
 - deriving seasonality parameters?
 - creating figures maps using these statistics

6 Exercise

- to be doable in 3 hours....
- combine concepts from previous lessons as well
- example 1: produce a figure with maximum/minimum/median/mean NDVI per year; figure should have a common scale and be properly labelled
